KURTI, N.

AUTHOR: KURTI, N., ROBINSON, F.N., SIMON, F., SPOR, D.A. PA - 2171
TITLE: Nuclear Cooling (Yadernoje okhlazdeniye, Russian)
PERIODICAL: Uspekhi Fiz. Nauk, 1957, Vol 61, Nr 1, pp 45-51 (U.S.S.R.)
Received: 3 / 1957 Reviewed: 4 / 1957

ABSTRACT: This paper was published in the original in Nature, 178, 450 (1956) and was translated by P.A.CHENCOV into Russian. Shortly after the first successful experiments concerning magnetic cooling it was suggested that a system of deeper temperatures be attained by the demagnetization of a system of nuclear spins, i.e. systems in which nuclear spins settle. The problem of realizability was investigated rather accurately by F.E.SIMON, Le Magnetism, 3, 1, Strasbourg, 1940. In accordance, magnetic field strengths of the order of 50.000 Ørsted and temperatures of the order 0,01° K are necessary for a perceptible reduction of the entropy of the nuclear system. The first part of all experiments concerning nuclear cooling has to consist of a magnetization, i.e. of the polarization of nuclear spin. For the orientation of nuclei atomic and molecular fields can be used, for which quite a series of methods was suggested. J. HATTON and B.V. ROLLIN, Proc.Roy.Soc.A 199, 222 (1949) began with the second stage of these experiments; they demagnetized a calcium fluoride crystal with an initial field strength (at 1,2° K) of up to 500 Ørsted. In this way they obtained 0,17° K. The authors of this paper believe to have approached more closely to their final aim. This aim consists in a perceptible reduction

Card 1/2

PA - 2171

Nuclear Cooling.

of the entropy of the system of nuclear spins under the action of an exterior magnetic field. By measuring the temperature obtained on the occasion of demagnetization, data concerning the nuclear interactions in solids could be obtained. Nuclear cooling occurs as follows: A substance with nuclear paramagnetism is magnetized in a strong magnetic field, on which occasion the liberated magnetization heat is absorbed by a "heat absorber". Magnetic field-strength is then reduced to zero, and if this process develops adiabatically, the system of nuclear spins cools down to a temperature which depends on the initial temperature, the strength of the applied magnetic field, and on nuclear interactions. The conditions for the utility of heat absorbers are discussed. The construction of the device is discussed and an illustration of the sample and the holder is attached. The carrying out of nuclear cooling is described. According to the results (demonstrated in a diagram) obtained, temperature differences of about $20 \cdot 10^{-6}$ ° K can be obtained. TITLE: The Triassic of the Caucasus (Trias Kavkaza)

PERIODICAL: V sb.: Tr. Vses. soveshchaniya po razrabotke unifitsir.
skhemy stratigr. mezozoyskikh otlozheniy Rus. platformy, Leningrad,
1956, pp 201-205

ABSTRACT: Small areas of Triassic rocks are known in the northern
Caucasus. In the 70 kilometer stretch along the trend of the Perekovyy
khrebet (range) and in a direction transverse to it, the full
Triassic section, with all its groups and series, is replaced
by a section of unconformable sedimentary formations having
sharply differing facies. The author proves that the geosynclinal
environment in this part of the Caucasus had given way to platform
conditions in the Middle Carboniferous. Not till the Lower
Jurassic was a new geosynclinal basin developed in this region.

1243. ROBINSON I. A. * Early morphological changes in experimental poliomyelitis (Russian text) Ž. NEVROPAT. PSIKHIIAT. (Mosk.) 1955, 55/2 (116-122) Illus. 3

Five apes were infected with poliomyelitis in different ways and sacrificed in the preparalytic stage. There were 2 distinct phases in the preparalytic stage. In 4 apes the nervous system was already affected in the first phase in that its central and peripheral, its motor and its afferent parts were involved, apart from the gen-

Inst. Neurology, A.Med.Sci., USSR

1243

CONT.

eral reaction of the organism and the changes in the internal organs. The morphology showed 2 components, viz: (1) diffuse unspecific changes (disturbances in the dynamics of the blood and the CSF, mild signs of inflammation in the soft meninges, reactions of the microglia) and (2) specific changes in the nerve cells. Special attention was given to the vascular changes in the CNS, which are typical of hypoxia of the cerebral tissue. The reaction of the microglia, of the trophic apparatus of the brain, occurs within the first stage and doubtlessly plays a role in the immunobiological adaptation of the organism. This stage also shows selective changes in the large neurons, rich in tigroid substance, and it is therefore probably in this early stage that the virus invading the nerve tissue is fixed in these cells, where it parasitically uses the abundant nucleoproteins for its propagation. The changes in the nerve cells precede the inflammatory changes in the soft meninges. In the second phase the morphology alters. The destruction of neurons and the inflammatory symptoms increase in severity. Examination of an ape which showed only slight paralysis of the facial muscles but no paralysis of extremities warrants the conclusion that the morphological picture is the same also in abortive cases. The pre-paralytic stage is regarded as a compensated poliomyelitic process. The disturbance in synapsis function is attributed to disturbances in the protein and phosphorus metabolism; this is of importance with a view to mediator treatment. Electromyography is important as an aid in early diagnosis, but increasing attention should be given to disturbances in sensitivity and vestibular function. Kalinowski has pointed out a tonic-clonic component in experimental nystagmus. The selective damage of certain neurons is based not only on their metabolism but also on the structure of their stroma.

Determination of unsaturated and aromatic compounds

In cracked gasoline. S. S. Naimetkin and E. A. Robinson,
Vestn. Khim. i Khim. Tekhnol. 24, 181-6, 230-3 (1933). The
authors carried out expts. on synthetic mixts. of 60-95%
cuts of dearomatized gasoline with various proportions
of cyclohexene, benzene and amyrene. It was found
that the completeness of removal of aromatic and unsatd.
compds. with H_2SO_4 depends upon the structure of the
unsatd. compds. present as well as on the ratio of the
above hydrocarbons in the mixt., and on the concn. and
the amt. of H_2SO_4 used. Thus, mixts. contg. about 20%
of cyclohexene and 15% C_6H_6 are freed from these hydro-
carbons after treatment by the Kattwinkel method, by
use of 3 parts of the mixt. and 1 part of the reagent and
shaking for 100 min. However, a mixt. contg. 20%
amyrene and 10% C_6H_6 still contains 8-10% of unsatd.
compds. Mixts. contg. relatively less unsatd. compds.
(50% of the aromatic compds.) contain 23% of polymeriza-
tion and condensation products which are not
removed by the above reagent. H_2SO_4 treatment with
acid of gradually increasing strength effects a removal of
some of the aromatic and unsatd. compds. while the Katt-
winkel reagent leaves 10%. When the Kattwinkel soln.
is used first, followed by treatment with H_2SO_4 and 1%
of SO_3 at -5° , 1.5% remains; repeated treatment
with oleum removes another 2% which indicates an
attack of satd. hydrocarbons. Narrow cuts of cracked
gasoline were treated with 80, 90, 94 and 98% H_2SO_4 with
1 vol. of gasoline and 2-3 vols. of acid with shaking for

20 min. In another series the Kattwinkel soln. was used.
The latter soln. was more effective than the H_2SO_4 , al-
though identical results were obtained with a preliminary
treatment with H_2SO_4 of lower strength followed by the
Kattwinkel treatment. The deviation of results obtained
by the H_2SO_4 method from that of the Kattwinkel method
may amount to 30%. In the detn. of unsatd. compds. in
the presence of aromatic compds., the H_2SO_4 cannot be
applied because of the attack of the H_2SO_4 on both aro-
matic and unsatd. hydrocarbons. The benzoyl peroxide
method was found to be very dependable with synthetic
mixts. such as menthene-gasoline, menthene-benzene,
limonene-menthane. The detn. of unsatd. compds. by
the above method in narrow cuts of cracked gasoline
showed deviations not exceeding 1%, provided that
30-50% of unsatd. compds. were present. A. A. R.

ASTM D-1 METALLURICAL LITERATURE CLASSIFICATION

Determination of unsaturated and aromatic compounds in cracked gasoline.
S. S. Nametkin and E. A. Robinson. *Neftegazov Khosyusno* 24, 292 (1933). After a rejection of the H_2SO_4 , the catalytic hydrogenation, the polymerization method with $ZnCl_2$, and the bromination method at low temp. because of their unreliability and detrimental action on the aromatics, the authors investigated the treatment with S_2Cl_2 recommended by Faragher, Morell and Levin (C. A. 24, 1208) (with some modifications). To 50 cc. of the mixt (synthetic) they added dropwise and under cooling 15 cc. of S_2Cl_2 . The excess of S_2Cl_2 was removed the next day with a 10% soln. of NaOH, and the hydrocarbon layer was distd. under ordinary pressure (up to 80-90°) which distd. over was then washed with NaOH and H_2O , dried over $CaCl_2$, and distd. over metallic Na. The aromatics were then detd. by the Kattwinkel method. The results were accurate within 0.3-0.5 per cent. However, if the concn. of unsaturates exceeds 25% the reaction cannot be controlled and the results are exaggerated. This can be avoided by diln. with gasoline. The Kattwinkel method should be applied to mixts. contg. up to 40% aromatics while for mixts. with only 0.5-2% the aniline method is best.

The method for volumetric determination of unsaturated and aromatic hydrocarbons in cracked gasoline - S. S. Nametkin, E. A. Robinson and V. P. Martynova. *Akhim Tsvetnoye Toplivo* 9, 77-85 (1981). The previously described app. (cf. *C. A.* 30, 7229) was somewhat modified, and the usual methods were used. The purpose was to find optimal conditions. Add (by drops) 70% by wt. of SCl_2 to the cracked gasoline while cooling in the ice bath. Allow to stand for 2-3 hrs. Add water (by drops), then 25% soln. of alkali, keeping the reaction mixt. well cooled. Finally, steam-dist. the unchanged portion of

the gasoline, collecting the distillate in a graduated cylinder. The difference in vol. between the sample used and the distillate is calc'd. as percentage for the content of unsatd. compds. The method is as accurate as the 1-no. method. To det. aromatic hydrocarbons, mix one vol. of gasoline with 3 vol. of the reagent (40 g. of P_2O_5 in 11 cc. of H_2SO_4 , of d. 1.84), while cooling in an ice bath for 30 min. (1st for 5 sec., then cool for 2-3 min., then for 15 min., cool again for 2-3 min., and so forth, gradually increasing the time of shaking to 3-5 min.). Then measure the vol. of gasoline in the upper layer and calc. as percentage by vol. A. A. Podgorny

APPENDIX A METALLURGICAL LITERATURE CLASSIFICATION

CA
22

Simplified method for determination of aromatic hydrocarbons in gasoline. E. A. Robinson and V. P. Martynov. *J. Applied Chem. (U.S.S.R.)* 12, 1297-72 in French, 1272(1959), Cl. C.I. 26, 1153. The method previously described was further investigated. The coeffs for the detn. of aromatic hydrocarbons in 4 fractions (at 20°, each about 30°) of gasoline by means of the method of equal vol. of gasoline and aniline were found. The following method is recommended for the detn. of aromatic hydrocarbons in gasoline (free from unsatd. compds.):
(1) Remove the aromatic hydrocarbons from one of the samples of gasoline with 2 vols of 98% H₂SO₄ at 0°. Wash gasoline with 10% alkali and water, dry over CaCl₂.
(2) Det. the temp. of dissolution of gasoline and aniline in above sample and original sample by the method of equal vol. Calc. the amt. of aromatic compds. (P in wt %) by the formula: $P = K(I_1 - I)$, where I_1 and I are aniline points of gasoline freed from aromatic compds. and of original sample, and K is the coeff. found by the method. Data are tabulated and plotted. — A. A. P.

The action of concentrated sulfuric acid on aromatic hydrocarbons of high molecular weight (S. S. Namotkin and I. N. Podgorny, *J. Applied Chem.* U. S. S. R., 12, 1438, 1960). The action of H_2SO_4 on a heptyl benzene, isooctylbenzene, octylbenzene, isooctylbenzene and isooctylnaphthalene and on their solns. in the petroleum oil fractions b, 100-70, was investigated. All these hydrocarbons were easily sulfonated with 98.2-100.0% sulfuric acid. However, the velocity of reaction depended on the structure of hydrocarbons and the concn. of H_2SO_4 . The sulfonic acids obtained were less sol. in H_2SO_4 than those obtained from the aromatic hydrocarbons of lower mol. wt. The mutual solv. of these sulfonic acids and hydrocarbons of other series was also quite limited; thus, emulsions and colloidal solns. were obtained in mixing these acids with the above oil fractions. Two layers were formed during sulfonation of the above hydrocarbons, the upper layer being the sulfonic acid layer.

The formation of sulfonic acid layer (between oil and acid layer) or partial soln. of sulfonic acids in the oil fraction was observed during the sulfonation of artificial mixts. of these hydrocarbons. The hydrocarbons of the petroleum (paraffin oil fractions) did not react with 100.6-100.8% sulfuric acid in the conditions used for the sulfonation of high-mol. hydrocarbons. The following method is recommended for the analysis of the oil fraction for the aromatic hydrocarbons which have a long paraffin chain. Treat twice the oil sample with 3 times its vol. 100.6-100.8% H_2SO_4 at 20° for 30 min. Det. the content of aromatic hydrocarbons by the change of vol. of oil, for completeness of the separ. of oil from sulfonic acids, should be used for extrn. of the sulfonic acids.

ASH-SEA METALLURGICAL LITERATURE CLASSIFICATION

Investigating the aromatic part of light lubricating-oil fractions. E. A. Robinson. *J. Applied Chem.* (U. S. S. R.) 13, 1852-1857 (1941).—Translated in *Foreign Petroleum Tech.* 9, 234-255, 256-264 (1941).—Fractions of Karachukhur crude oil b. 200-400° contain from 12 to 14% aromatic hydrocarbons, while the same fractions from Balakhany crude oil contain 30-32% aromatic hydrocarbons. The aromatic hydrocarbons from both crude oils (b. 160-200°, 1 mm.) are free from aromatics with long side chains of the fatty series such as cetylbenzene and cetylhydridene, as well as cetylaphthalene and dioctyl-naphthalene. The above finding was confirmed by sulfonation, which yielded in all cases H_2SO_4 -sol. sulfonic acids. The av. compn. of aromatic hydrocarbons present in the fraction b. 130-160° (1 mm.) corresponds either to fractions. This permits assuming that this type of hydrocarbons the bicyclic aromatics with an aliphatic chain, or to carbon, the mol. of which contains simultaneously aro- monocyclic hydrocarbons with naphthalene cycles in the matus and naphthalene cycles and also the paraffin chain, side chain. When both types are present the av. compn. corresponds properly to the mean compn. of the aromatic of the aromatic part corresponds to aromatic hydrocarbons part of the crude oil, provided the total of cycles is not be- greater than 3. The same conclusions are arrived at with the frac- tions with 2 aromatic cycles, one naphthalene ring and an low 3. The same conclusions are arrived at with the frac- tions with 3 aromatic rings and a corresponding length of the continent crude oil and they are close to Karachukhur with 3 aromatic rings and a corresponding length of the continent crude oil and they are close to Karachukhur and Balakhany oils. The consts. of monocyclic and bi- and 1 aliphatic chain, or 2 aromatic, 2 naphthalene cycles cyclic aromatics with long paraffin chains are very different and 1 paraffin chain. Hydrocarbons having in their mol. from the aromatic part of lubricating oil fractions of Grozny 1 aromatic ring, 1 naphthalene ring and a paraffin chain mixed and asphalt-base crudes and of Surakhan, Rimba (for example, heptylhydridene and phenylhexyleylene) and Balakhany crude oils, while bicyclic aromatics with naphthalene pentane have different consts. from those of aromatics shorter chains or monocyclic aromatics with naphthalene present in Karachukhur and Balakhany crude oils. Evi-cycles (side chains) are close to the aromatic hydrocarbons dendy, the av. compn. of the oils under investigation cor- of the original fractions. Fifteen references. A. A. Bochlinik

TITLE: Investigation of Hydrocarbons of Naphthalene Series in the Kerosene Fraction of oil from the Romashkinskoye Oil Field in the Minnibayevskaya Area. (Issledovaniye uglevodorodov ryadya naftalina v kerosinovoy fraktsii nefti Romashkinskogo mestorozhdeniya Minnibayevskoy ploschchadi)

PERIODICAL: Khimiya i Tekhnologiya Topliv i Masel, 1953, Nr 9, pp 18 - 24, (USSR)

ABSTRACT: The kerosene fractions of Devonian Tartar petrol contain considerable quantities of aromatic hydrocarbons. Investigations were carried out with the aid of the pirate method and ultra-violet spectra of condensed hydrocarbons of the kerosene fraction (200° - 320°) of Romashkino petroleum. This fraction was separated by chromatography on silica gel ASK (50 - 100 mesh) into a naphthenic-paraffinic fraction and aromatic concentrate. The latter was divided into monocyclic and dicyclic compounds. The sulphur-containing compounds were separated by oxidising the aromatic concentrate with hydrogen peroxide in a medium of glacial acetic acid and the oxidised sulphur-containing compounds adsorbed on silica gel ASK. The desulphurised aromatic hydrocarbons were vacuum

distilled into three - five-grade fractions in a 37-plate column. Each fraction was treated with picric acid and the naphthalene hydrocarbons were separated. The homologues of naphthalene were separated by rectification, and in some cases the isomers were also split off. The liquid isomers were separated by repeated recrystallization from ethyl or methyl alcohol and subjected to further decomposition. The crystalline hydrocarbons were purified by repeated recrystallization from methyl alcohol. The separated hydrocarbons were identified by elementary analysis and by comparing the physical constants and melting points of secondary picrates with literature data. The individual naphthalene hydrocarbons, as well as mixtures of isomers, were further subjected to spectral analysis of the near ultra-violet region (2,900 - 3,500 Å). The absorption spectra were measured on the spectrophotometer SF-4 (in n-pentane solution) (Fig. on page 19). Constants of the separated hydrocarbons are given in a table (pages 20 and 21). The separated hydrocarbons consisted of naphthalene, β -methylnaphthalene,
